

香港中文大學(深圳)

The Chinese University of Hong Kong, Shenzhen

Introduction to Computer Science: Programming Methodology

Midterm Review

Prof. Pinjia He

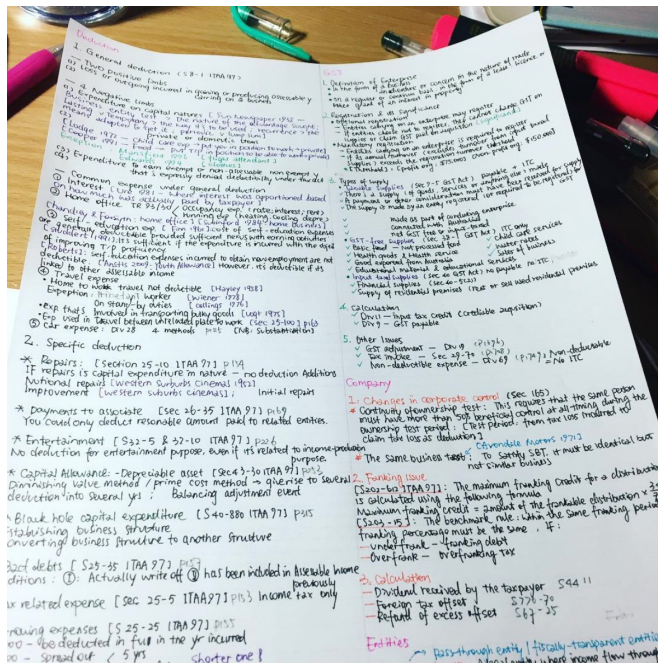

School of Data Science

Scope

- Lecture **1** – Lecture **5** (List)
- Question: MC, Short-answer questions

Cheat sheet

- A4 paper **both sides**
- Hand-written or printed

Tips about cheat sheet

- **Concepts** on the cheat sheet

Central Processing Unit

- A processor contains two units, a control unit (CU) and an arithmetic/logic unit (ALU)
- **CU** is used to fetch commands from the memory
- **ALU** contains the electric circuits which can execute commands

Tips about cheat sheet

- **Resize** the images/screenshots

Tips about cheat sheet

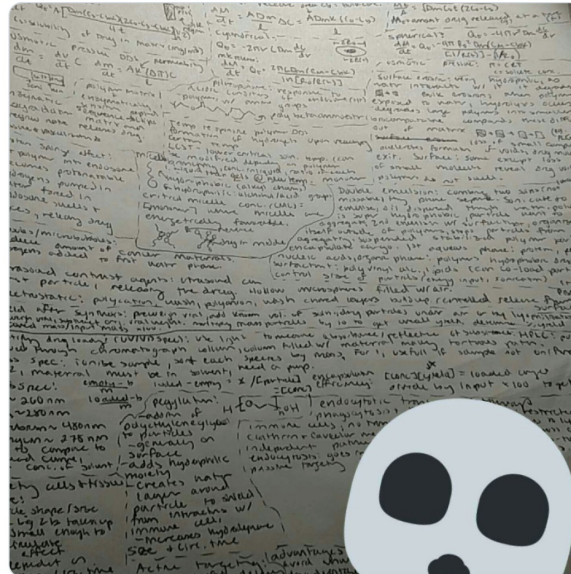

- Make sure you **can find** the right place

wow
@themainyvette

When your cheat sheet looks like this you know you have no faith in yourself

Details!

★ careful look!!

"Hello world" v.s. "Hello world"

空格.

1+1 v.s. '1'+'1'

2 11

a = '113'

a[1] = '2'

print(a) X

string不可修改.

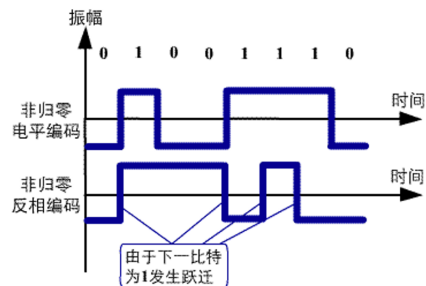

Everything from slides

What can a computer actually understand?

- The computers used nowadays can understand only binary number (i.e. 0 and 1)
- Computers use voltage levels to represent 0 and 1
- NRZL and NRZI coding
- The instructions expressed in binary code is called **machine language**

(Video: Programming Languages)

0 0 0 1	numerical value 2^0
0 0 1 0	numerical value 2^1
0 1 0 0	numerical value 2^2
1 0 0 0	numerical value 2^3

Other tips

- Carefully read the question, whether it ask you to select **ONE** or allows **MULTIPLE**
- Write down what you know
- **Example**(s) on your cheat sheet

Other tips

- Practice makes perfect :)
- Start **early**

MC

Concerning Von Neumann Architecture, which is the following is incorrect?

- A. It has central processing unit ✓
- B. It has memory unit ✓
- C. It has HDMI cable
- D. It has input device ✓

MC

Concerning Von Neumann Architecture, which is the following is incorrect?

- A. It has central processing unit
- B. It has memory unit
- C. It has HDMI cable
- D. It has input device

MC

Concerning C++, which is the following is incorrect?

- ☒ A. Inherent major features of C
- ☒ B. It is an object-oriented programming language
- ☒ C. It is powerful in low level memory manipulation
- ☐ D. It is usually slower than Python

MC

Concerning C++, which is the following is incorrect?

- A. Inherent major features of C
- B. It is an object-oriented programming language
- C. It is is powerful in low level memory manipulation
- D. It is usually slower than Python

MC

A

Binary number 1001.001 equals to the decimal number

A. 9.125

B. 18.125

C. 9.25

D. 18.25

$$\begin{aligned} & 1 \times 2^0 + 0 + 0 + 1 \times 2^3 + 0 + 0 + 1 \times 2^{-3} \\ & = 1 + 8 + 0.125 \end{aligned}$$

Hexadecimal to binary

Decimal to hexadecimal

Which of the following is X?

Which of the following is NOT X?

Which of the following is correct/incorrect?

What is the output of the following program?

What is the value of variable x at line 2?

...

Short-answer questions

Read the following program and answer the related questions:

```
1 emailHeader = 'From/professor.xman@uct.edu/Sat/Jan/5/09:14:16/2008'
2 words = emailHeader.split()
3
4 print(words)           ["professor.xman", "uct.edu"]
5
6 address = words[1].split('@')
7
8 print(address)
9 print(address[1])      uct.edu
```

```
1 emailHeader = 'From professor.xman@uct.edu Sat Jan 5 09:14:16 2008'
2 words = emailHeader.split()
3
4 print(words)
5
6 address = words[1].split('@')
7
8 print(address)
9 print(address[1])
```

What can this program do?

What is the data type of variable **words**?

What will be printed at **line 4**?

```
['From', 'professor.xman@uct.edu', 'Sat', 'Jan', '5', '09:14:16', '2008']
['professor.xman', 'uct.edu']
uct.edu
```

What will be printed at **line 8**?

What is the value of variable **words** at **line 8**?

What is the difference between **split()** and **split('@')**?

```
['professor.xman@uct.edu']
```

What will be the value of variable **address** if we use **split()** instead of **split('@')** at **line 6**?

What will be the **output** for running **line 9** if we use **split()** instead of **split('@')** at **line 6**?

...

The units of information (data)

- Bit (比特/位): a binary digit which takes either 0 or 1
- Bit is the smallest information unit in computer programming
- Byte (字节): 1 byte = 8 bits, every English character is represented by 1 byte
- KB (千字节): $1 \text{ KB} = 2^{10} \text{ B} = 1024 \text{ B}$
- MB (兆字节): $1 \text{ MB} = 2^{20} \text{ B} = 1024 \text{ KB}$
- GB (千兆字节): $1 \text{ GB} = 2^{30} \text{ B} = 1024 \text{ MB}$
- TB (兆兆字节): $1 \text{ TB} = 2^{40} \text{ B} = 1024 \text{ GB}$

All functions introduced

- `divmod()`
- `str()`
- `input()`
- `print()`
- `eval()`
-

Here we list those mentioned in lec2 as examples.

All operators introduced

Operator	Description	Syntax
+	Addition: adds two operands	$x + y$
-	Subtraction: subtracts two operands	$x - y$
*	Multiplication: multiplies two operands	$x * y$
/	Division (float): divides the first operand by the second	x / y
//	Division (floor): divides the first operand by the second	$x // y$
%	Modulus: returns the remainder when first operand is divided by the second	$x \% y$
**	Power : Returns first raised to power second	$x ** y$

Here we list the arithmetic operators as examples.

Variable

- A variable is a **named space** in the **memory** where a programmer can store **data** and later retrieve the data using the **variable name**

Constants

- Fixed values such as numbers and letters are called **constants**, since their values won't change
- String** constants use single-quotes (') or double-quotes (")

Reserved words

- You **cannot** use the following words as **variables**

False	None	True	and	as	assert	break
class	continue	def	del	elif	else	except
finally	for	from	global	if	import	in
is	lambda	nonlocal	not	or	pass	raise
return	try	while	with	yield		

Assignment statement

- There is a location in the memory for x
- Whenever the value of x is needed, it can be retrieved from the memory
- After the expression is evaluated, the result will be put back into x

Order evaluation

- When we put operators together, Python needs to know which one to do first
- This is called “operator precedence”
- Which operator “takes precedence” over the others

Example: $X = 1 + 2 * 3 - 4 / 5 ** 6$

$1 + 2 \times 3 - \underline{4}$

fb

Data Type

- In Python, variables and constants have an associated “**type**”
- Python **knows the difference** between a number and a string

• **Example:**

```
>>> a = 100 + 200
>>> print(a) 300

>>> b = "100" + "200"
>>> print(b) 100200
```

Comments

- Anything after a “#” is ignored by Python
- Why comment?
 - ✓ Describe **what is going to happen** in a sequence of code
 - ✓ Document **who wrote the code** and other important information
 - ✓ **Turn off** a line of code – usually temporarily

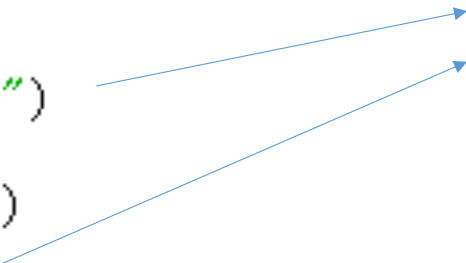

Conditional flow

Program

```
x=5
if x<10:
    print("smaller")
if x>20:
    print("bigger")
print("finished")
```

Outputs

```
smaller
finished
>>> |
```

Two way decision using else

```
x=1  
  
if x>2:  
    print(' Bigger' )  
  
print(' Finished' )
```

Multi-way decision

```
x=56
if x<2:
    print(' Small')
elif x<10:
    print(' Medium')
elif x<20:
    print(' Large')
elif x<40:
    print(' Huge')
else:
    print(' Ginormous')

print(' Finished')
```

Comparison operators

- **Boolean expressions** ask a question and produce a **Yes/No** result, which we use to **control program flow**
- **Boolean expressions** use **comparison operators** to evaluate Yes/No or True/False
- **Comparison operators** check variables but do not change the values of variables
- **Careful!!** “=” is used for assignment

$x < y$	Is x less than y?
$x \leq y$	Is x less than or equal to y?
$x == y$	Is x equal to y?
$x \geq y$	Is x greater than or equal to y?
$x > y$	Is x greater than y?
$x \neq y$	Is x not equal to y?

Logical operators

- Logical operators can be used to combine several logical expressions into a single expression
- Python has three logical operators: not, and, or

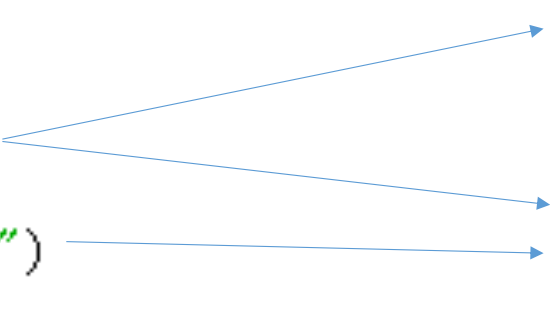

Repeated flow

Program

```
n=5
while n>0:
    print(n)
    n = n - 1
print("Finish")
```

Outputs

```
5
4
3
2
1
Finish
>>>
```

- Loops (repeated steps) have iterative variables that change each time through a loop
- Often these iterative variables go through a sequence of numbers

Breaking out of a loop

- The break statement ends the current loop, and jumps to the statement which directly follows the loop

```
while (True):  
    line = input('Enter a word:')  
    if line == 'done':  
        break  
    print(line)  
print('Finished')
```

Finishing an iteration with continue

```
while True:
    line = input('Input a word:')
    if line[0] == '#': continue
    if line == 'done':
        break
    print(line)
print('Done')
```

- The **continue** statement ends the current iteration, and **start the next iteration immediately**

For loop

Example

```
for i in [5, 4, 3, 2, 1]:  
    print(i)  
print('Finished')
```

Output

```
5  
4  
3  
2  
1  
Finished
```

- **For loops (definite loops)** have explicit iteration variables that change each time through a loop.
- These iteration variables move through a sequence or a set

Indentation 缩进

- **Increase indent**: indent after an **if** or **for** statement (after :)
- **Maintain indent**: to indicate the **scope** of the block (which lines are affected by the **if/for**)
- **Decrease indent**: to **back to** the level of the if statement or for

```
x=5
print('Before 5')
if x==5:
    print('Is 5')
    print('Is still 5')
    print('Third 5')

print('Afterwards 5')
```

Use try/except to capture errors

```
astr = 'Hello bob'
try:
    istr = int(astr)
except:
    istr = -1
print('First', istr)
```

```
astr = '123'
try:
    istr = int(astr)
except:
    istr = -1
print('Second', istr)
```

- When the first conversion **fails**, it just **stops into the except block**, and the program continues
- When the second conversion **succeeds**, it just **skips the except block**

Argument

```
big = max('Hello world')
```

w

Result

```
>>> big = max('Hello world')
>>> print(big)
w
>>> small = min('Hello world')
>>> print(small)
```

Scope of variables

- The **scope** of a variable is the part of program where this variable can be accessed

```
globalVar = 1
def f1():
    localVar = 2
    print(globalVar)
    print(localVar)
```

- A variable created inside a function is referred to as a **local variable**

```
f1()
print(globalVar)
print(localVar) # Out of scope, so this gives an error
```

- **Global variables** are created outside all functions and are accessible to all functions in their scope

} local ?
| global ?

Rules for defining variables in Python

- Must start with a letter or underscore _

`courseName` `_courseName`

- Can **only** contain letters, numbers and underscore

`course~Name`

- Case **sensitive**

`courseName` `coursename`

- **Good**: apple, car, myNumber123, _light

- **Bad**: 456aaa, #ab, var.12

字母, 数字, 下划线

- **Different**: apple, Apple, APPLE

Looking inside strings

- We can get **any character** in a string using an **index** specified in **square brackets**
- The index value must be an **integer** which starts from **zero**
- The index value can be an **expression**

b	a	n	a	n	a
0	1	2	3	4	5

```
>>> fruit = 'banana'
>>> letter = fruit[1]
>>> print letter
a
>>> n = 3
>>> w = fruit[n - 1]
>>> print w
n
```

String operations

- Some operators **apply to strings**

✓ **“+”**: concatenation

✓ **“*”**: multiple concatenation

- Python **knows** whether it is dealing with a number or a string

Index out of range

- You will get an **Python error** if you attempt to index beyond the end of a string

```
>>> name = 'Junhua'
>>> name[6]
Traceback (most recent call last):
  File "<pyshell#10>", line 1, in <module>
    name[6]
IndexError: string index out of range
```

- Be careful when specifying an index value

Looking inside lists

- Just like strings, we can access any **single element** in a list using an **index** specified in square bracket

Joseph	Glenn	Sally
0	1	2

```
>>> friends = ['Joseph', 'Glenn', 'Sally']  
>>> print(friends[1])  
Glenn
```

Concatenating lists using +

- Similar to strings, we can **add** two existing lists together to create a **new list**

```
>>> a=[1, 2, 3]
>>> b=[4, 5, 6]
>>> c=a+b
>>> print(c)
[1, 2, 3, 4, 5, 6]
>>> print(a)
[1, 2, 3]
```

Lists can be sliced using :

- Remember: similar to strings, the second number is “up to but not including”

```
>>> t=[9, 41, 12, 3, 74, 15]
>>> t[1:3]
[41, 12]
>>> t[:4]
[9, 41, 12, 3]
>>> t[3:]
[3, 74, 15]
>>> t[:]
[9, 41, 12, 3, 74, 15]
```

Dictionary

- Lists **index** their entries based on the position in the list
- **Dictionaries** are like bags – no order
- We **index** the elements we put in the dictionary with a “lookup tag”

```
>>> purse = dict()
>>> purse['money'] = 12
>>> purse['candy'] = 3
>>> purse['tissues'] = 75
>>> print(purse)
{'money': 12, 'tissues': 75, 'candy': 3}
>>> print(purse['candy'])
3

>>> purse['candy'] = purse['candy'] + 2
>>> print(purse)
{'money': 12, 'tissues': 75, 'candy': 5}

>>> purse[3] = 77
>>> print(purse)
{3: 77, 'money': 12, 'tissues': 75, 'candy': 5}
```

Tuples

- Tuples are another type of sequence that function more like a list – they have elements which are indexed starting from 0

```
>>> x=('Glenn','Sally','Joseph')
>>> print(x)
('Glenn', 'Sally', 'Joseph')
>>> y=(1, 9, 2)
>>> print(y)
(1, 9, 2)
>>> print(max(y))
9
```

```
>>> for i in y:
    print(i)

1
9
2
```

File processing

- A text file can be thought of as a **sequence of lines**
- A text file has **newline** at the end of each line

```

```

File handle as a sequence

- A file **handle** open for read can be treated as a **sequence of strings** where each line in the file is a string in the sequence

```
fhand = open('myhost.txt', 'r')  
  
for line in fhand:  
    print(line)
```

```
fhand.close()
```

- We can use the **for** statement to loop through a sequence
